Abstract. Schur superpolynomials have been introduced recently as limiting cases of the Macdonald superpolynomials. It turns out that there are two natural super-extensions of the Schur polynomials: in the limit $q = t = 0$ and $q = t \rightarrow \infty$, corresponding respectively to the Schur superpolynomials and their dual. However, a direct definition is missing. Here, we present a conjectural combinatorial definition for both of them, each being formulated in terms of a distinct extension of semi-standard tableaux. These two formulations are linked by another conjectural result, the Pieri rule for the Schur superpolynomials. Indeed, and this is an interesting novelty of the super case, the successive insertions of rows governed by this Pieri rule do not generate the tableaux underlying the Schur superpolynomials combinatorial construction, but rather those pertaining to their dual versions. As an aside, we present various extensions of the Schur bilinear identity.

Key words: symmetric superpolynomials; Schur functions; super tableaux; Pieri rule

1 Introduction

1.1 Schur polynomials

The simplest definition of the ubiquitous Schur polynomials is combinatorial [13, I.3] (and also [14, Chapter 4]). For a partition λ , the Schur polynomial $s_\lambda(x)$, where x stands for the set (x_1, \dots, x_N) , is the sum over monomials weighted by the content of semi-standard tableaux T with shape λ (whose set is denoted $\mathcal{T}(\lambda)$):

$$s_\lambda(x) = \sum_{T \in \mathcal{T}(\lambda)} x^T, \quad (1.1)$$

with $x^T \equiv x^\alpha = x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_N^{\alpha_N}$, where α is a composition of weight $|\lambda|$ (the sum of all the parts of λ) and represents the content of T , namely T contains α_i copies of i . For instance, in three variables,

$$s_{(2,1)}(x) = x_1^2 x_2 + x_1 x_2^2 + x_1^2 x_3 + x_1 x_3^2 + x_1 x_2 x_3 + x_1 x_2 x_3,$$

where each term is in correspondence with a semi-standard tableau:

$$\begin{array}{|c|c|} \hline 1 & 1 \\ \hline 2 & \\ \hline \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 2 & \\ \hline \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 1 \\ \hline 3 & \\ \hline \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 3 & \\ \hline \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 3 & \\ \hline \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 2 & \\ \hline \end{array}.$$

The number of semi-standard tableaux of shape λ and content μ (where μ is also a partition) is the Kostka number $K_{\lambda\mu}$. Relation (1.1) can thus be rewritten

$$s_\lambda(x) = \sum_{\alpha} K_{\lambda\mu} x^\alpha = \sum_{\mu \leq \lambda} K_{\lambda\mu} m_\mu(x),$$

where $\mu = \alpha^+$, the partition obtained by ordering the parts of the composition α in weakly decreasing order. In the last equality, the symmetric character of the Schur polynomial is used to reexpress them in terms of the monomial symmetric polynomials $m_\mu(x)$,

$$m_\mu(x) = x_1^{\mu_1} \cdots x_N^{\mu_N} + \text{distinct permutations}, \quad (1.2)$$

and the order in the summation is the dominance order: $\lambda \geq \mu$ if and only if $|\lambda| = |\mu|$ and $\sum_{i=1}^k (\lambda_i - \mu_i) \geq 0$ for all k .

A closely related approach for constructing the Schur polynomials is based on the Pieri formula. The latter refers to the decomposition in Schur polynomials of the product of two Schur polynomials, one of which being indexed by a single-row partition, say $s_{(k)}$. Schur polynomials can thus be constructed from the identity by multiplying successive $s_{(k)}$'s. Recall that $s_{(k)} = h_k$, where h_k stands for the completely homogeneous symmetric polynomials:

$$h_k(x) = \sum_{1 \leq i_1 \leq \cdots \leq i_k \leq N} x_{i_1} \cdots x_{i_k},$$

to which is associated the multiplicative basis $h_\mu = h_{\mu_1} h_{\mu_2} \cdots h_{\mu_N}$ (with $h_0 = 1$). The link between the Pieri rule and the above definition of the Schur polynomials is

$$s_{(\mu_1)} s_{(\mu_2)} \cdots s_{(\mu_N)} = h_{\mu_1} h_{\mu_2} \cdots h_{\mu_N} = h_\mu(x) = \sum_{\lambda \geq \mu} K_{\lambda\mu} s_\lambda(x).$$

In other words, by filling the rows μ_i with number i and applying the Pieri rule from left to right to evaluate the multiple product of the $s_{(\mu_i)}$, amounts to construct semi-standard tableaux. Then, isolating the term s_λ from the complete product is equivalent to enumerate the semi-standard tableaux of shape λ and content μ .

The objective of this work is to present conjectured combinatorial definitions of the Schur superpolynomials and their dual. In addition, we present the conjectural version of the Pieri rule for Schur superpolynomials. By duality, the resulting tableaux are not those appearing in the combinatorial description of the Schur superpolynomials but rather those of their dual version.

1.2 Schur superpolynomials

Superpolynomials refer to polynomials in commuting and anticommuting variables (respectively denoted x_i and θ_i) and their symmetric form entails invariance under the simultaneous permutation of the two types of variables. The classical symmetric functions are generalized in [7]. Super-analogues of the Jack and Macdonald symmetric polynomials appear as eigenfunctions of the Hamiltonian of the supersymmetric extension of the Calogero–Sutherland (cf. [5, 6]) and the Ruijsenaars–Schneider (cf. [3]) models respectively.

Denote the Macdonald superpolynomials by $P_\Lambda = P_\Lambda(x, \theta; q, t)$, where Λ is a superpartition (cf. Section A.1), (x, θ) denotes the $2N$ variables $(x_1, \dots, x_N, \theta_1, \dots, \theta_N)$ and q, t are two arbitrary parameters. P_Λ is defined from [2]:

- 1) $P_\Lambda = m_\Lambda + \text{lower terms}$,
- 2) $\langle P_\Lambda, P_\Omega \rangle_{q,t} \propto \delta_{\Lambda\Omega}$,

where lower terms are w.r.t. the dominance order between superpartitions (cf. Definition A.4), m_Ω stands for the super-monomial (cf. Definition A.5) and the scalar product is defined in terms of the power-sum basis p_Λ (cf. Definition A.6, equation (A.1)) with

$$\langle p_\Lambda, p_\Omega \rangle_{q,t} := \delta_{\Lambda\Omega} (-1)^{\binom{m}{2}} z_\Lambda(q, t), \quad z_\Lambda(q, t) = z_{\Lambda^s} q^{|\Lambda^a|} \prod_i \frac{1 - q^{\Lambda_i^s}}{1 - t^{\Lambda_i^s}}, \quad (1.3)$$

where we used the representation $\Lambda = (\Lambda^a; \Lambda^s)$ with m being the number of parts of Λ^a , and $z_\Lambda = \prod_i i^{n_i(\lambda)} n_i(\lambda)!$ where $n_i(\lambda)$ is the number of parts equal to i in λ . Two special limits of the P_Λ are of particular interest, namely

$$s_\Lambda(x, \theta) := P_\Lambda(x, \theta; 0, 0) \quad \text{and} \quad \bar{s}_\Lambda(x, \theta) := P_\Lambda(x, \theta; \infty, \infty). \quad (1.4)$$

That s_Λ and \bar{s}_Λ are different objects follows from the fact that

$$P_\Lambda(x, \theta; q, t) \neq P_\Lambda(x, \theta; q^{-1}, t^{-1}) \quad \text{since} \quad z_\Lambda(q^{-1}, t^{-1}) \neq f(q, t)^{|\Lambda|} z_\Lambda(q, t)$$

for some monomial $f(q, t)$. We refer to the functions s_Λ and \bar{s}_Λ as the Schur superpolynomials and the dual Schur superpolynomials respectively.

A closer look at (1.4) shows that these are not at once sound definitions since in both limits, the scalar product (1.3) is ill-defined. However, a deeper investigation relying on [9, 11] reveals that both limiting forms of the Macdonald superpolynomials turn out to be well behaved and this results in the expression of s_Λ and \bar{s}_Λ in terms of key polynomials (see [1, Appendix A]).

Here we present an alternative and direct – albeit conjectural – combinatorial definition for both s_Λ and \bar{s}_Λ . It relies on the observation that the elements of the transition matrices between the s_Λ , \bar{s}_Λ and the super-monomial basis are all non-negative integers [2, Conjecture 6]. In other words, we have that

$$s_\Lambda = \sum_{\Lambda \geq \Omega} \bar{K}_{\Lambda\Omega} m_\Omega, \quad \bar{s}_\Lambda = \sum_{\Lambda \geq \Omega} K_{\Lambda\Omega} m_\Omega$$

with $\bar{K}_{\Lambda\Omega}, K_{\Lambda\Omega} \in \mathbb{N}$.¹ The integral positivity of these coefficients hints for an underlying combinatorial description for both s_Λ and \bar{s}_Λ . The presentation of such a combinatorial description is the main result of this work. The expansion coefficients $\bar{K}_{\Lambda\Omega}$ and $K_{\Lambda\Omega}$ are obtained by enumerating appropriate generalizations of semi-standard tableaux. Despite the fact that there is no known representation theory underlying these new generalizations of the Schur functions, we expect that the present tableau construction will pave the way for the elaboration of a super-version of the Robinson–Schensted–Knuth correspondence.

The article is organized as follows. We first introduce the notion of super semi-standard tableaux in Section 2. Those tableaux of shape Λ are the building blocks for defining the *combinatorial* Schur superpolynomial s_Λ^c , presented in Section 3. The construction readily implies the symmetric nature of s_Λ^c and its triangular decomposition in the monomial basis. The Pieri rule for the s_Λ is given in Section 4. In Section 5 we introduce the dual super semi-standard tableaux whose enumeration describes (conjecturally) the dual version \bar{s}_Λ . The link with Pieri tableaux that arise in the multiple application of the Pieri rule for Schur superpolynomials is spelled out in Section 6. Two appendices complete this article. The first is a review of the necessary tools concerning superpartitions and the classical bases in superspace. In Appendix B, we present a collection of generalized bilinear identities for Schur superpolynomials.

¹The somewhat unnatural position of the bar over $K_{\Lambda\Omega}$ with respect to that over s_Λ follows the notation of [2]. The functions s_Λ are used to define a novel positivity conjecture [10] in superspace (see [2, Conjecture 9]). If we denote by J_Λ the integral version of the Macdonald superpolynomials ($J_\Lambda = c_\Lambda P_\Lambda$ with $c_\Lambda \in \mathbb{Z}(q, t)$) and $S_\Lambda(t) = \varphi(s_\Lambda)$, where $\varphi(\cdot)$ is the homomorphism that send $p_r \rightarrow (1 - t^r)p_r$, we obtain that

$$J_\Lambda = \sum_{\Omega} K_{\Omega\Lambda}(q, t) S_\Omega(t), \quad K_{\Omega\Lambda}(q, t) \in \mathbb{N}(q, t).$$

Setting $q = 0, t = 1$ in $K_{\Omega\Lambda}(q, t)$ gives the number $K_{\Omega\Lambda}$ that appears in the super-monomial expansion of \bar{s}_Ω (not s_Ω). Note that there is no relation between the numbers $\bar{K}_{\Lambda\Omega}$ and $K_{\Lambda\Omega}$ except that they both reduce to ordinary Kostka numbers for $m = 0$.

$$\begin{array}{cccccc}
\Box & \Box & \Box & \Box & 2 & 2 \\
\Box & \Box & \Box & 2 & 1 & \\
1 & 1 & 1 & \textcircled{1} & & \\
\Box & \Box & & & & \\
\textcircled{2} & & & & &
\end{array}, \quad
\begin{array}{cccccc}
\Box & \Box & \Box & \Box & \Box & \Box \\
\Box & \Box & 2 & 2 & 1 & \\
1 & 1 & 1 & \textcircled{1} & & \\
\Box & 2 & & & & \\
\textcircled{2} & & & & &
\end{array}. \quad (2.2)$$

For the tableau on the left, the number 2 in box $(1, 5)$ belongs to a doublet since it can be coupled with the 1 in position $(2, 5)$; the remaining two 2 are singlets. (The 2 in the doublet could as well be taken to be the one in position $(1, 6)$.) Note that the three 1 in the third row cannot be parts of doublets being in a fermionic row. In the second tableau, the three 2 are singlets. As we just remarked, the characterization of a doublet is not unique. However, their number is well defined and this implies that the number of singlets is also well defined. It is precisely the number of singlets that is relevant here.

Rule 2.4 (fermionic numbers in bosonic rows). Let $c_{k,0}$ and $c_{k,k-1}$ be respectively the number of bosonic columns at the right of the fermionic column ending with a circled i_k and the number of bosonic columns between the two fermionic columns ending with circled i_k and i_{k-1} . The occurrence of i_k in boxes of bosonic rows must satisfy the two conditions:

- (a) i_k can only appear at the (upper) right of the fermionic column ending with circle i_k ;
- (b) i_k can appear at most $c_{k,0}$ times but at most $c_{k,k-1}$ times as singlet.

For instance, the tableau at the right in (2.2) does not satisfy this rule since there can be at most two singlets 2 given that $c_{2,1} = 2$. As a further example, notice that

<table style="border-collapse: collapse; text-align: center;"> <tr><td></td><td></td><td></td><td></td></tr> <tr><td></td><td></td><td></td><td></td></tr> <tr><td></td><td></td><td></td><td>3</td></tr> <tr><td></td><td></td><td>1</td><td></td></tr> <tr><td></td><td>2</td><td></td><td></td></tr> <tr><td>3</td><td></td><td></td><td></td></tr> </table>												3			1			2			3				and	<table style="border-collapse: collapse; text-align: center;"> <tr><td></td><td></td><td></td><td></td></tr> <tr><td></td><td></td><td></td><td>3</td></tr> <tr><td></td><td></td><td></td><td>2</td></tr> <tr><td></td><td></td><td>1</td><td></td></tr> <tr><td></td><td>2</td><td></td><td></td></tr> <tr><td>3</td><td></td><td></td><td></td></tr> </table>								3				2			1			2			3				are not allowed but	<table style="border-collapse: collapse; text-align: center;"> <tr><td></td><td></td><td></td><td>3</td></tr> <tr><td></td><td></td><td></td><td>2</td></tr> <tr><td></td><td></td><td></td><td>1</td></tr> <tr><td></td><td></td><td>1</td><td></td></tr> <tr><td></td><td>2</td><td></td><td></td></tr> <tr><td>3</td><td></td><td></td><td></td></tr> </table>				3				2				1			1			2			3				is allowed.
			3																																																																										
		1																																																																											
	2																																																																												
3																																																																													
			3																																																																										
			2																																																																										
		1																																																																											
	2																																																																												
3																																																																													
			3																																																																										
			2																																																																										
			1																																																																										
		1																																																																											
	2																																																																												
3																																																																													

Indeed, since $c_{3,2} = 0$, the 3 cannot be a singlet. In the second tableau the 3 is part of a doublet but now $c_{2,1} = 0$ requires the 2 to be coupled with 1.

Rule 2.5 (semi-standard filling). The bosonic rows are filled with numbers in I using the ordering defined in Rule 2.2 and such that numbers in rows are weakly increasing and strictly increasing in columns (disregarding the frozen numbers in fermionic rows).

Definition 2.2. A tableau T° satisfying Rules 2.1–2.5 is called a super semi-standard tableau.

Here is an example

<table style="border-collapse: collapse; text-align: center;"> <tr><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td></tr> <tr><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td><td>2</td></tr> <tr><td>6</td><td>6</td><td>7</td><td>8</td><td>5</td><td></td><td></td><td></td><td></td><td></td></tr> <tr><td>3</td><td>3</td><td>3</td><td>3</td><td>3</td><td></td><td></td><td></td><td></td><td></td></tr> <tr><td>7</td><td>7</td><td>8</td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr> <tr><td>4</td><td>4</td><td>4</td><td>4</td><td>4</td><td></td><td></td><td></td><td></td><td></td></tr> </table>	1	1	1	1	1	1	1	1	1	1	2	2	2	2	2	2	2	2	2	2	6	6	7	8	5						3	3	3	3	3						7	7	8								4	4	4	4	4						.	(2.3)
1	1	1	1	1	1	1	1	1	1																																																					
2	2	2	2	2	2	2	2	2	2																																																					
6	6	7	8	5																																																										
3	3	3	3	3																																																										
7	7	8																																																												
4	4	4	4	4																																																										

When fermionic numbers appear in bosonic rows, being larger than the bosonic numbers, they occupy the rightmost positions (and by consequence, the downmost positions in columns). Once all fermionic numbers have been inserted, it is convenient to work with a reduced diagram, or, if filled, a reduced tableau.

Definition 2.3 (reduced tableau). The reduced tableau of T° , denoted T_{red}° , is the tableau obtained from T° by removing all circles and all the boxes marked by fermionic numbers and tighten all rows.

The numbers in boxes of the reduced tableau satisfy the ordinary semi-standard tableau conditions for the numbers in the set I_m^c . In other words, T_{red}° is a genuine semi-standard tableau. For the example (2.3), T_{red}° is simply

3 The combinatorial Schur superpolynomials

In this section, we introduce a new family of functions, dubbed the combinatorial Schur superpolynomials s_Λ^c . They are defined in terms of the tableaux introduced in the previous section. That these functions are indeed equal to the Schur superpolynomials defined in (1.4) is the main (conjectural) result of this section.

Let Λ be of degree $(n|m)$. We defined a monomial ζ^{T° in the variables (x, θ) associated to the tableau T° by introducing a factor x_i for each number i appearing in a box and a θ_j for a circled j , the circle content being read from top to bottom:

$$\zeta^{T^\circ} := \theta_{I_m} \prod_{i \in T^*} x_i$$

with $\theta_{I_m} = \theta_{i_1} \cdots \theta_{i_m}$ and T^* denotes the box content of T° . For instance, the monomial corresponding to the tableau (2.3) is

$$\theta_1 \theta_2 \theta_3 \theta_4 \theta_5 x_1^8 x_2^6 x_3^3 x_4^2 x_5 x_6^2 x_7^3 x_8^2.$$

Definition 3.1. The combinatorial Schur superpolynomial $s_\Lambda^c = s_\Lambda^c(x, \theta)$ is given by

$$s_\Lambda^c := \sum_{T^\circ \in \mathcal{T}^\circ(\Lambda)} \zeta^{T^\circ}, \quad (3.1)$$

where $\mathcal{T}^\circ(\Lambda)$ denotes the set of super semi-standard tableaux of shape Λ .

The upper script c refer to the combinatorial definition: s_Λ^c might differ in principle from s_Λ defined in (1.4).

For example, $s_{(0;2,1)}^c$ is obtained by summing the contribution of the tableaux:

$$\begin{array}{|c|c|} \hline 2 & 2 \\ \hline 3 & \\ \hline \textcircled{1} & \end{array}, \quad \begin{array}{|c|c|} \hline 2 & 3 \\ \hline 3 & \\ \hline \textcircled{1} & \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 1 \\ \hline 3 & \\ \hline \textcircled{2} & \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 3 & \\ \hline \textcircled{2} & \end{array}, \quad \dots, \quad \begin{array}{|c|c|} \hline 2 & 1 \\ \hline 3 & \\ \hline \textcircled{1} & \end{array}, \quad \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 3 & \\ \hline \textcircled{2} & \end{array}, \quad \dots, \quad \begin{array}{|c|c|} \hline 2 & 3 \\ \hline 4 & \\ \hline \textcircled{1} & \end{array}, \quad \begin{array}{|c|c|} \hline 2 & 4 \\ \hline 3 & \\ \hline \textcircled{1} & \end{array}, \quad \dots,$$

whose variable transcription reads

$$\theta_1 x_2^2 x_3 + \theta_1 x_2 x_3^2 + \theta_2 x_1^2 x_3 + \theta_2 x_1 x_3^2 + \cdots + \theta_1 x_1 x_2 x_3 + \theta_2 x_1 x_2 x_3 + \cdots + 2\theta_1 x_2 x_3 x_4 + \cdots.$$

In order to show that the superpolynomials s_Λ^c can be written in the basis of the monomial superpolynomials, their symmetric character must first be established.

Proposition 3.1. *The superpolynomial s_Λ^c is symmetric.*

Proof. It suffices to show that s_Λ^c is invariant under elementary transpositions, e.g.:

$$(i, i+1)s_\Lambda^c = s_\Lambda^c,$$

where $(i, i+1)$ is the permutation that exchanges simultaneously $x_i \leftrightarrow x_{i+1}$ and $\theta_i \leftrightarrow \theta_{i+1}$. This action is lifted to tableaux as follows. Consider the involution: $T^\circ \rightarrow \tilde{T}^\circ$ such that the number

of boxes marked with i 's and the number of boxes marked with $(i+1)$'s are exchanged from T° to \tilde{T}° . Two cases need to be described.

(1) If i and $i+1$ are bosonic numbers (i.e. $\in I_m^c$), the involution only transforms the reduced tableaux, which are semi-standard. In that case, the involution is taken to be the usual one (see, e.g., [14, Proposition 4.4.2]). The tableau reconstructed from the modified reduced tableau is manifestly an element of $\mathcal{T}^\circ(\Lambda)$.

(2) If i and/or $i+1 \in I_m$, the operation simply amounts to interchange all the numbers i and $i+1$ in T° . In that case, the ordering within the set I_m is modified and the new filling is automatically an element of $\mathcal{T}^\circ(\Lambda)$. ■

To substantiate the conjectural equivalence of s_Λ^c and s_Λ (cf. Conjecture 3.1 below), we demonstrate the unitriangularity of s_Λ^c in its super-monomial expansion.

Proposition 3.2. *We have*

$$s_\Lambda^c = \sum_{\Omega} \bar{K}_{\Lambda\Omega}^c m_\Omega, \quad (3.2)$$

where $\bar{K}_{\Lambda\Omega}^c$ is the number of super semi-standard tableaux of shape Λ and content Ω , with

$$\bar{K}_{\Lambda\Omega}^c = \begin{cases} 0 & \text{if } \Omega \not\preceq \Lambda, \\ 1 & \text{if } \Omega = \Lambda. \end{cases} \quad (3.3)$$

Proof. Since s_Λ^c is symmetric, the decomposition (3.1) can be rewritten as an expansion in terms of the monomials m_Ω (which form a basis for symmetric superpolynomials [7]). As a result, the expression (3.2) follows directly from the definition of $\bar{K}_{\Lambda\Omega}^c$ as the number of elements of $\mathcal{T}^\circ(\Lambda)$ having content Ω . What has to be shown then is the statement (3.3), i.e., that the expansion is unitriangular.

At first, observe that one can focus on tableaux for which $I_m = \{1, \dots, m\}$ and with box content $(1^{\Omega_1}, 2^{\Omega_2}, \dots, N^{\Omega_N})$ in order to identify the multiplicity of the monomial m_Ω since:

$$m_\Omega = \theta_1 \cdots \theta_m x_1^{\Omega_1} \cdots x_N^{\Omega_N} + \text{distinct permutations.}$$

Now, consider all the different monomials m_Ω appearing in the expansion of s_Λ^c , cf. equation (3.2). First, consider those fillings of Λ such that no fermionic numbers appear in bosonic rows. In this case, the content $\Omega = (\Omega^a; \Omega^s)$ is necessarily such that $\Omega^a = \Lambda^a$. We are left with the filling of reduced diagrams of shape Λ^s and content Ω^s . In other words, we have

$$\bar{K}_{(\Lambda^a; \Lambda^s)(\Lambda^a; \Omega^s)}^c = K_{\Lambda^s, \Omega^s},$$

where K_{Λ^s, Ω^s} , being indexed by two ordinary partitions, refers the usual Kostka numbers. The unitriangularity of the K_{Λ^s, Ω^s} 's proves the triangularity of $\bar{K}_{\Lambda\Omega}^c$ for the special case where $\Omega^a = \Lambda^a$ and it implies that $\bar{K}_{\Lambda\Lambda}^c = 1$.

Next, consider the case where $\Omega^a \neq \Lambda^a$. By construction, we have $\Omega^a > \Lambda^a$ (with respect to the dominance ordering for partitions but relaxing the constraint $|\Omega^a| = |\Lambda^a|$). Indeed, the numbers k within a row, say i , ending with the circle k are frozen and some extra k may be inserted in the upper-right part of the tableau; therefore $\Omega_i^a \geq \Lambda_i^a$. Suppose that one fermionic number k is introduced in row i . Focussing on the tails of the two rows concerned here, we have:

$$\begin{array}{ccc} \cdots \begin{array}{|c|c|c|c|c|} \hline & & & & \\ \hline \end{array} & \rightarrow & \cdots \begin{array}{|c|c|c|c|c|} \hline & & & & k \\ \hline \end{array} \\ \cdots \begin{array}{|c|} \hline k \\ \hline \end{array} & \rightarrow & \cdots \begin{array}{|c|c|} \hline & \\ \hline k & k \\ \hline \end{array} \end{array} \quad \begin{array}{l} \text{part of } \Lambda \\ \text{with a marked circle} \end{array} \quad \begin{array}{l} \text{part of content } \Omega \end{array} \quad \begin{array}{l} \text{part of shape } \Omega \end{array}$$

Clearly, the relation between Λ and Ω is as follows: the diagram of Ω is obtained from that of Λ by moving a box downward from a bosonic to a fermionic row. This operation satisfies $\Lambda^* \geq \Omega^*$ and $\Lambda^\circ \geq \Omega^\circ$ so that $\Lambda \geq \Omega$ (cf. Definition A.4). Indeed, it suffices to compare the superpartitions composed of the two concerned rows: $(b; a) \in \Lambda$ and $(b+1; a-1) \in \Omega$, with $a > b$, and testing successively the truncated version of $\Lambda^* \geq \Omega^*$ and $\Lambda^\circ \geq \Omega^\circ$:

$$(a, b) \geq (a-1, b+1) \quad \text{and} \quad (a, b+1) \geq (a-1, b+2) \quad \implies \quad (b; a) \geq (b+1; a-1).$$

Now consider inserting several k in the same row (here 3)

In the final step, at the level of the shapes of the corresponding diagrams, a box has moved downward from a bosonic to a fermionic row and a circle has moved up. A computation similar to the above one consists in comparing the two-row superpartitions $(b; a)$ and $(a-1; b+1)$ for $a > b$; we see that

$$(a, b) \geq (a-1, b+1) \quad \text{and} \quad (a, b+1) \geq (a, b+1) \quad \implies \quad (b; a) \geq (a-1; b+1)$$

from which it follows that $\Lambda^* \geq \Omega^*$ and $\Lambda^\circ \geq \Omega^\circ$. Since these two processes can be done iteratively, the action of filling several boxes of bosonic rows with fermionic numbers always produce terms of lower degree with respect to the dominance ordering. ■

We now turn to some examples illustrating the construction of the combinatorial object s_Λ^c . For all the examples, we identify the leading term of a super-monomial and consider thus only those tableaux T_m° for which all circles are filled with the numbers $(1, \dots, m)$, from top to bottom.

Example 3.1. The case of a purely fermionic superpartition. Here there is a single contributing monomial:

$$s_{(\Lambda^a;)}^c = m_{(\Lambda^a;)}.$$

Indeed, there are no bosonic rows so that there is only one contributing tableau T_m° where all the boxes are frozen, all marked i in row i .

Example 3.2. The case of a superpartition where (Λ^a, Λ^s) is a partition (i.e., $\Lambda_m \geq \Lambda_{m+1}$). Then we have

$$s_\Lambda^c = \sum_{\Omega^s \leq \Lambda^s} K_{\Lambda^s, \Omega^s} m_{(\Lambda^a; \Omega^s)}.$$

Here the bosonic rows of Λ^s all lie below the fermionic ones. Since the fermionic number k cannot appear in rows below the one ending with circled k , there cannot be any occurrence of the fermionic numbers in the bosonic rows. These bosonic boxes are then filled with numbers in the set $\{m+1, \dots, N\}$, generating usual semi-standard tableaux enumerated by the usual Kostka coefficients.

Example 3.3. A simple case: $\Lambda = (1; 4)$. With $I_1 = \{1\}$, the filled tableaux are (note that here $1 > 4 > 3 > 2$):

$$\begin{array}{ccccc}
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 2 & 2 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 2 & 3 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 3 & 3 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 3 & 4 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 3 & 4 & 5 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} \\
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 2 & 1 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 3 & 1 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 3 & 4 & 1 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 2 & 1 & 1 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array} &
\begin{array}{|c|c|c|c|} \hline 2 & 3 & 1 & 1 \\ \hline 1 & \textcircled{1} & & \\ \hline \end{array}
\end{array} \tag{3.4}$$

giving then

$$s_{(1;4)}^c = m_{(1;4)} + m_{(1;3,1)} + m_{(1;2,2)} + m_{(1;2,1,1)} + m_{(1;1,1,1,1)} \\ + m_{(2;3)} + m_{(2;2,1)} + m_{(2;1,1,1)} + m_{(3;2)} + m_{(3;1,1)}.$$

In the above expression, the ordering of the monomials follows that of the tableaux listed in (3.4). Here $m = 1$ and Ω_1^a is the number of boxes marked with 1 (these are identified with a part in Ω^a since the circle is filled with 1). Then, the number of 2 gives the value of Ω_1^s , the number of 3 yields Ω_2^s and so on.

Example 3.4. Here is a more complicated example, choosing $I_2 = \{1, 2\}$:

$$\Lambda = (3, 0; 4, 1) \quad \begin{array}{|c|c|c|c|} \hline & & \cdot & \cdot \\ \hline 1 & 1 & 1 & \textcircled{1} \\ \hline & & & \\ \hline \textcircled{2} & & & \\ \hline \end{array}.$$

Since $c_{2,1} = 2$, there can be at most two 2 appearing in positions indicated with dotted boxes. There is thus three possible fillings with fermionic numbers:

$$\Omega^a = (3, 0) : \begin{array}{|c|c|c|c|} \hline & & & \\ \hline 1 & 1 & 1 & \textcircled{1} \\ \hline & & & \\ \hline \textcircled{2} & & & \\ \hline \end{array} \quad \Omega^a = (3, 1) : \begin{array}{|c|c|c|c|} \hline & & & 2 \\ \hline 1 & 1 & 1 & \textcircled{1} \\ \hline & & & \\ \hline \textcircled{2} & & & \\ \hline \end{array} \quad \Omega^a = (3, 2) : \begin{array}{|c|c|c|c|} \hline & & 2 & 2 \\ \hline 1 & 1 & 1 & \textcircled{1} \\ \hline & & & \\ \hline \textcircled{2} & & & \\ \hline \end{array}$$

with corresponding reduced diagrams $(4, 1)$, $(3, 1)$ and $(2, 1)$. We thus read

$$s_{(3,0;4,1)}^c = \sum_{\Omega^s \leq (4,1)} K_{(4,1),\Omega^s} m_{(3,0;\Omega^s)} + \sum_{\Omega^s \leq (3,1)} K_{(3,1),\Omega^s} m_{(3,1;\Omega^s)} \\ + \sum_{\Omega^s \leq (2,1)} K_{(2,1),\Omega^s} m_{(3,2;\Omega^s)}, \quad (3.5)$$

so that

$$s_{(3,0;4,1)}^c = m_{(3,0;4,1)} + m_{(3,0;3,2)} + 2m_{(3,0;3,1,1)} + 2m_{(3,0;2,2,1)} + 3m_{(3,0;2,1,1,1)} \\ + 4m_{(3,0;1,1,1,1,1)} + m_{(3,1;3,1)} + m_{(3,1;2,2)} + 2m_{(3,1;2,1,1)} + 3m_{(3,1;1,1,1,1)} \\ + m_{(3,2;2,1)} + 2m_{(3,2;1,1,1)}.$$

We now end this section with the announced conjecture that identifies the Schur superpolynomials defined combinatorially, namely s_{Λ}^c , with those obtained from Macdonald superpolynomials for $q = t = 0$, denoted s_{Λ} (cf. (1.4)).

Conjecture 3.1. *We have $s_{\Lambda}^c(x, \theta) = s_{\Lambda}(x, \theta)$. Equivalently, $\bar{K}_{\Lambda\Omega}^c = \bar{K}_{\Lambda\Omega}$.*

This conjecture has been extensively tested. In particular, all the examples presented in this section agree with the statement of the conjecture.

4 The Pieri rule

We now present a conjectural version of the Pieri rule for the Schur superpolynomials s_{Λ} defined by (1.4). In order to formulate the rule, we must recall the notion of horizontal and vertical k -strips: a horizontal (resp. vertical) k -strip is a skew diagram that has at most one square in each column (resp. row) [13]. In the following, we need an extension that includes circles.

Definition 4.1 ((\overline{k}) -strips). A horizontal (\overline{k}) -strip is a horizontal k -strip augmented by a circle in its upper-right position; straightened horizontally, it represents the diagram of the superpartition $(k;)$. A vertical (\overline{k}) -strip is a vertical k -strip augmented by a circle in its lower-left position; straightened vertically, it represents the diagram of the superpartition $(0; 1^k)$.

Here are some examples of strips made of boxes marked by \star :

(4.1)

representing respectively, a horizontal $(\overline{3})$ -strip, a vertical $(\overline{4})$ -strip and a 3-strip that is both horizontal and vertical. The Pieri rule relies on a specific rule, spelled out in the following, for the multiplication of a row or a column diagram with a generic diagram.

Rule 4.1 (Multiplication of a row/column with a diagram Λ).

- I. Row multiplication: the squares and the circle (if the row is fermionic) that are added to the diagram Λ must form a horizontal strip, in addition to generate an admissible resulting diagram (i.e., rows are weakly decreasing and there can be at most one circle per row and column). Moreover, when inserting the squares of a row into the diagram of Λ , the circles of Λ can be displaced subject to the following restrictions:
 - (i) a circle in the first row can be moved horizontally without restrictions;
 - (ii) a circle not in the first row can be moved horizontally as long as there is a square in the row just above it in the original diagram Λ (i.e., the circle in row i can be displaced by at most $\Lambda_{i-1}^* - \Lambda_i^* - 1$ columns);
 - (iii) a circle can be displaced vertically in the same column by at most one row.
- II. Column multiplication: interchange ‘row’ and ‘column’, ‘horizontal’ and ‘vertical’, ‘above’ and ‘at the left’ in I.

Definition 4.2 (Pieri diagrams). Let Λ and Γ be two superpartitions, with Γ a row or a column diagram (bosonic or fermionic). We denote by $\Lambda \otimes \Gamma$ the set of all admissible diagrams, called Pieri diagrams, obtained by the multiplication of Γ with the diagram of Λ using Rule 4.1.

Note that a strip of either type needs not to be located completely on the exterior (or right) boundary of the larger diagram. However, when the circles are erased, the strip is indeed at the exterior frontier of the diagram, which is clear from the examples (4.1).

Now, consider for example the multiplication of a bosonic row of length 3 with the diagram of $\Lambda = (2, 0; 1)$, operation being denoted by

where the boxes of the diagram $(; 3)$ are marked by 1. Using Rule 4.1, the resulting Pieri

(4.2)

$$\begin{array}{|c|c|} \hline & \\ \hline \end{array} \otimes \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline \end{array} : \begin{array}{|c|c|} \hline & \\ \hline \end{array} \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline \end{array}, \begin{array}{|c|c|c|} \hline & & 1 \\ \hline \end{array} \begin{array}{|c|} \hline 2 \\ \hline \end{array}, \begin{array}{|c|c|} \hline & \\ \hline \end{array} \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline \end{array}, \begin{array}{|c|c|c|} \hline & & 1 \\ \hline \end{array} \begin{array}{|c|} \hline 2 \\ \hline \end{array}, \begin{array}{|c|c|} \hline & \\ \hline \end{array} \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline \end{array}, \quad (4.3)$$
$$s_{\Lambda} s_{(r)} = \sum_{\Omega \in \Lambda \otimes (r)} s_{\Omega} \quad \text{and} \quad s_{\Lambda} s_{(r;)} = \sum_{\Omega \in \Lambda \otimes (r;)} (-1)^{\# \ell_{\odot}} s_{\Omega} \quad (4.4)$$
$$s_\Lambda s_{(;1r)} = \sum_{\Omega \in \Lambda \otimes (;1r)} s_\Omega \quad \text{and} \quad s_\Lambda s_{(0;1r)} = \sum_{\Omega \in \Lambda \otimes (0;1r)} (-1)^{\# \ell_\odot} s_\Omega.$$

Here are some examples illustrating these Pieri formulas.

Example 4.1. Consider the product $s_{(4,0;3)}s_{(3;)}.$ Using the multiplication Rule 4.1, we find the following diagrammatic Schur superpolynomials expansion:

$$\begin{array}{c} \begin{array}{|c|c|c|c|} \hline & & & \\ \hline & & & \\ \hline & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \times \begin{array}{|c|c|c|c|} \hline 1 & 1 & 1 & 1 \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} = \begin{array}{c} \begin{array}{|c|c|c|c|c|c|} \hline & & & & 1 & 1 \\ \hline & & & & 1 & \\ \hline & & & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} + \begin{array}{c} \begin{array}{|c|c|c|c|c|} \hline & & & & 1 \\ \hline & & & & \\ \hline & & & & \\ \hline & & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|c|c|} \hline & & & & 1 \\ \hline & & & & \\ \hline & & & & \\ \hline & & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|c|c|} \hline & & & & 1 \\ \hline & & & & \\ \hline & & & & \\ \hline & & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ - \begin{array}{c} \begin{array}{|c|c|c|c|c|} \hline & & & & \\ \hline & & & & \\ \hline & & & & \\ \hline & & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \end{array} \end{array} \quad (4.5)$$

Note that the last tableau appears with a minus sign since there is one circle below the added one (marked with 1)². Written in terms of the Schur superpolynomials, this reads

$$s_{(4,0;3)}s_{(3;)} = s_{(6,4,0;)} + s_{(5,4,1;)} + s_{(5,4,0;1)} - s_{(4,3,0;3)}.$$

Remark. Here one might wonder why no tableau appears where the bottom unmarked circle is moved horizontally by two units (which is permitted by the length of the row just above) in (4.5). The only option would be

$$\begin{array}{|c|c|c|c|c|} \hline & & & & 1 \\ \hline & & & & \\ \hline & & & & \\ \hline 1 & 1 & & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} .$$

But the building strip is not a horizontal 3-strip: its upper-right component is a square and not a circle.

Example 4.2. Consider next the product $s_{(1;2,1)}s_{(0;1,1,1)}$ and fill the column of the second diagram with numbers 1 to 4. Using the Pieri formula, we have

$$\begin{array}{c} \begin{array}{|c|c|} \hline & \\ \hline & \\ \hline & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \times \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline 3 \\ \hline 4 \\ \hline \end{array} = \begin{array}{c} \begin{array}{|c|c|c|} \hline & & \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \\ + \begin{array}{c} \begin{array}{|c|c|c|} \hline & & 1 \\ \hline & & \\ \hline & & \\ \hline & & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array} \begin{array}{c} \circ \\ \circ \end{array} \end{array} \end{array} \quad (4.6)$$

The third and fourth tableaux illustrate the vertical motion of the circle. The fifth and sixth tableaux exemplify the allowed horizontal move by one column even if it exceeds the number of squares of the previous row in the original tableau as long as this upper slot is occupied by a square of the strip (here the square marked 1). Note that in all cases, the circle marked 4 is below the unmarked one: the factor $\# \ell_{\odot}$ is 0 in all diagrams, so that we have

$$s_{(1;2,1)}s_{(0;1^3)} = s_{(1,0;2,1^4)} + s_{(1,0;3,1^3)} + s_{(1,0;2^2,1^2)} + s_{(1,0;3,2,1)} + s_{(2,0;3,1^2)} + s_{(2,0;3,2)}.$$

Remark. Note that the following tableau

$$\begin{array}{|c|c|} \hline & \\ \hline & 1 \\ \hline & 2 \\ \hline 3 & \\ \hline 4 & \\ \hline \end{array} \begin{array}{c} \circ \\ \circ \end{array}$$

²The origin of the relative sign is clear from the algebraic point of view: since a circle is associated with a factor θ (the anticommuting variables), we see that, compared with the first three diagrams, the last one is associated with a different ordering of the first two θ factors. Upon reordering, this yields the minus sign.

is not allowed in the decomposition (4.6) since the top circle has moved vertically by two units. This is forbidden because that gives the circle a position exceeding the number of squares in the first column (cf. point II(ii) of Rule 4.1).

Example 4.3. Finally, from the examples (4.2), (4.3), we read off:

$$\begin{aligned} s_{(2,0;1)}s_{(;3)} &= s_{(5,0;1)} + s_{(4,0;2)} + s_{(4,0;1,1)} + s_{(3,0;2,1)} + s_{(2,0;3,1)} + s_{(2,0;4)}, \\ s_{(2,0;1)}s_{(3;)} &= s_{(4,2,0;0)} + s_{(3,2,0;1)}, \\ s_{(2,0;1)}s_{(;1^2)} &= s_{(2,0;1^3)} + s_{(3,0;1^2)} + s_{(2,0;2,1)} + s_{(3,0;2)} + s_{(2,1;2)}, \\ s_{(2,0;1)}s_{(0;1^2)} &= s_{(2,1,0;2)}. \end{aligned}$$

Let us compare the tableaux resulting from the successive applications of the row-version of the Pieri rule with the super semi-standard tableaux described in Section 2. Consider for instance a complete filling of the tableau at the left in (2.2)

3	3	3	5	2	2
4	4	4	2	1	
1	1	1	①		
5	5				
②					

for which the ordering is $1 > 2 > 5 > 4 > 3$. Clearly, there is no way to remove successively horizontal strips composed of 1, and then of 2, 5, etc. Therefore, although the Pieri rule builds up Schur superpolynomials, there is no relation between the Kostka numbers $\bar{K}_{\Lambda\Omega}$ and this Pieri rule. It turns out that the latter is directly related to the *dual* semi-standard tableaux enumerated by the Kostka numbers $K_{\Lambda\Omega}$, namely, the expansion coefficients of the dual Schur superpolynomials \bar{s}_Λ in the monomial basis. These dual tableaux are introduced in Section 5.

5 The combinatorial dual Schur superpolynomials

In this section, we introduce a second family of combinatorial functions, \bar{s}_Λ^c , defined in terms of a dual counterpart of the super semi-standard tableaux. The main result here is the conjectural equivalence of these new functions with the \bar{s}_Λ .

5.1 Dual super semi-standard tableaux

We thus first introduce the dual tableaux. The qualitative *dual* refers to the way the fermionic numbers are ordered and the rules for their insertion in the tableau. Rule 2.1 still holds and the set I_m is defined as before, as the ordered set of the labels in circles read from top to bottom. But Rule 2.2 is replaced by its dual.

Rule 5.1 (dual ordering in the set I). The numbers in the set I_m are still considered to be the m largest numbers of the set I but they are now ordered as $i_m > i_{m-1} > \dots > i_1$ (and $i_1 > j \forall j \in I_m^c$). In I_m^c , the ordering is the natural one.

For example (2.1), this yields $5 > 1 > 3 > 14 > 13 > \dots > 2$.

As already indicated, the rules for the filling of the fermionic numbers are also modified. At first, the numbers in the fermionic rows are no longer frozen. In addition, the fermionic number i_k , when appearing in a bosonic row, is forbidden in the squares at the upper-right of the circled i_k ; it can only appear in the dual region, at its lower-left. This is made precise in the following.

Rule 5.2 (fermionic numbers). The occurrence of the fermionic numbers in boxes must satisfy the following conditions:

- a) the number i_k can only appear at the left of the column ending with circled i_k ;
- b) the fermionic number $i_{k-\ell}$, with $\ell \geq 1$, must appear above or at the right of the circled i_k at least ℓ times;
- c) counting the boxes from right to left and top to bottom, the number of boxes marked i_k must always be strictly greater than those marked i_{k+1} .

For instance, the fermionic filling (with $I_2 = \{1, 2\}$) of the shape $(5, 3; 1)$ and content $(3, 2; 1^4)$ are

To illustrate Rule 5.2b, consider the diagram $(8, 4, 2, 0; 6, 3, 3, 1, 1)$ and the two fermionic fillings of content $\Omega^a = (4, 2, 1, 0)$:

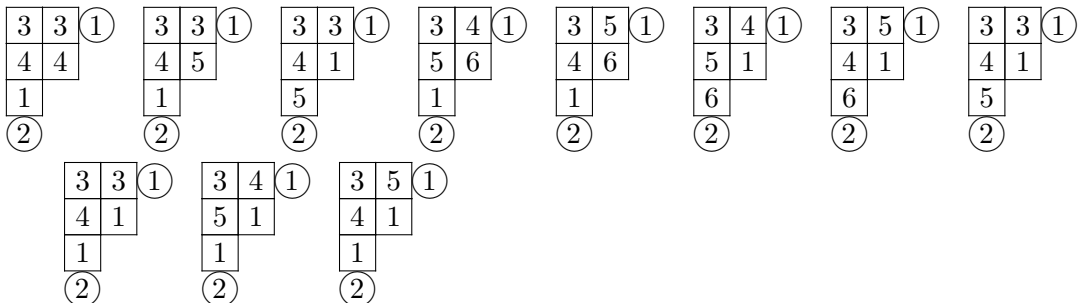

Let AR stands for ‘above or at the right’. The conditions on the appearance of the number 1 are: once AR of 2, twice AR of 3, three times AR of 4. Similarly, the number 2 must appear at least once AR of 3, and twice AR of 4, while the 3 must appear once AR of 4. The tableau at the left satisfies all the conditions but not the one at the right (the first condition on the number 2 is violated).

Finally, Rule 2.5 needs to be trivially modified as follows.

Rule 5.3 (dual semi-standard filling). The boxes are filled with numbers in I using the ordering defined in Rule 5.1 and such that numbers in rows are weakly increasing and strictly increasing in columns.

Definition 5.1. A tableau \bar{T}° satisfying Rules 2.1, 5.1, 5.2 and 5.3 is called a dual super semi-standard tableau.

For instance, the dual semi-standard tableaux with shape $\Lambda = (2, 0; 2, 1)$ and $I_2 = \{1, 2\}$ are

Notice that at least one box must have 1 (i.e., set $k = 2$ and $\ell = 1$ in Rule 5.2b) and none can have 2.

5.2 Combinatorial definition of the dual Schur superpolynomials

We are now in position to define the combinatorial dual Schur superpolynomials.

Definition 5.2. The combinatorial dual Schur superpolynomial $\bar{s}_\Lambda^c = \bar{s}_\Lambda^c(x, \theta)$ is defined as

$$\bar{s}_\Lambda^c := \sum_{\bar{T}^\circ \in \bar{\mathcal{T}}^\circ(\Lambda)} \zeta^{\bar{T}^\circ},$$

where $\bar{\mathcal{T}}^\circ(\Lambda)$ is the set of dual semi-standard tableaux of shape Λ .

For example, the superpolynomial $\bar{s}_{(1;2)}^c$ is obtained from the tableaux:

$$\begin{array}{ccccccc} \begin{array}{|c|c|} \hline 2 & 2 \\ \hline 1 & \textcircled{1} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 1 & 1 \\ \hline 2 & \textcircled{2} \\ \hline \end{array} & , & \dots & , & \begin{array}{|c|c|} \hline 2 & 3 \\ \hline 1 & \textcircled{1} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 2 & \textcircled{2} \\ \hline \end{array} & , & \dots & , & \begin{array}{|c|c|} \hline 2 & 2 \\ \hline 3 & \textcircled{1} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 1 & 1 \\ \hline 3 & \textcircled{2} \\ \hline \end{array} & , & \dots \\ \begin{array}{|c|c|} \hline 2 & 3 \\ \hline 4 & \textcircled{1} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 2 & 4 \\ \hline 3 & \textcircled{1} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 4 & \textcircled{2} \\ \hline \end{array} & , & \begin{array}{|c|c|} \hline 1 & 4 \\ \hline 3 & \textcircled{2} \\ \hline \end{array} & , & \dots \end{array}$$

which reads

$$\begin{aligned} & \theta_1 x_1 x_2^2 + \theta_2 x_1^2 x_2 + \dots + \theta_1 x_1 x_2 x_3 + \theta_2 x_1 x_2 x_3 + \dots + \theta_1 x_2^2 x_3 \\ & + \theta_2 x_1^2 x_3 + \dots + 2\theta_1 x_2 x_3 x_4 + 2\theta_2 x_1 x_3 x_4 + \dots \end{aligned}$$

Proposition 5.1. The \bar{s}_Λ^c are symmetric superpolynomials.

The proof follows that establishing the symmetric character of s_Λ^c (cf. Proposition 3.1) and will be omitted.

Proposition 5.2. We have

$$\bar{s}_\Lambda^c = \sum_{\Omega} K_{\Lambda\Omega}^c m_\Omega,$$

where $K_{\Lambda\Omega}^c$ is the number of elements of $\bar{\mathcal{T}}^\circ(\Lambda)$ with content Ω and it satisfies

$$K_{\Lambda\Omega}^c = \begin{cases} 0 & \text{if } \Omega \not\leq \Lambda, \\ 1 & \text{if } \Omega = \Lambda. \end{cases}$$

This proof will also be omitted.

Example 5.1. Let us evaluate the number $K_{(8,4;1,1),(6,3;1^5)}^c$. The allowed fermionic-number fillings, with $I_2 = \{1, 2\}$, are

$$\begin{array}{ccc} \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & 1 & 1 & 1 & 1 & 1 & 1 \\ \hline & 2 & 2 & 2 & & & & \textcircled{1} \\ \hline & & & & & & & \\ \hline & & & & & & & \\ \hline \end{array} & , & \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & & & 1 & 1 & 1 & 1 \\ \hline & 1 & 2 & 2 & & & & \textcircled{1} \\ \hline 1 & & & & & & & \\ \hline 2 & & & & & & & \\ \hline \end{array} & , & \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & 1 & 1 & 1 & 1 & 1 & 1 \\ \hline & & 2 & 2 & & & & \textcircled{1} \\ \hline & & & & & & & \\ \hline 2 & & & & & & & \\ \hline \end{array} \\ \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & & 1 & 1 & 1 & 1 & 1 \\ \hline & & 2 & 2 & & & & \textcircled{1} \\ \hline 1 & & & & & & & \\ \hline 2 & & & & & & & \\ \hline \end{array} & , & \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & & 1 & 1 & 1 & 1 & 1 \\ \hline & 1 & 2 & 2 & & & & \textcircled{1} \\ \hline & & & & & & & \\ \hline 2 & & & & & & & \\ \hline \end{array} & , & \begin{array}{|c|c|c|c|c|c|c|c|} \hline & & & 1 & 1 & 1 & 1 & 1 \\ \hline & 2 & 2 & 2 & & & & \textcircled{1} \\ \hline & & & & & & & \\ \hline 1 & & & & & & & \\ \hline \end{array} \end{array}$$

The multiplicity of each tableau is equal to the multiplicity of the corresponding reduced standard (i.e., with all entries being distinct) tableaux. This gives multiplicity 4 for the first two tableaux, 5 to the following two and 6 for the remaining ones which gives a total of 30, i.e., $K_{(8,4;1,1),(6,3;1^5)}^c = 30$.

Conjecture 5.1. *We have $\bar{s}_\Lambda^c = \bar{s}_\Lambda$. Equivalently, $K_{\Lambda\Omega}^c = K_{\Lambda\Omega}$.*

Although there is no relation between the two versions of the Schur superpolynomials, the next section reveals a striking indirect connection.

6 Relating the Pieri rule to dual semi-standard tableaux

As indicated at the end of Section 4, the Pieri tableaux obtained by successive row multiplications do not correspond to super semi-standard tableaux. They are rather related to their dual versions. This is a consequence of the nontrivial duality property of the Schur superpolynomials. Let $\langle \cdot, \cdot \rangle$ be the scalar product (1.3) with $q = t = 1$:

$$\langle p_\Lambda, p_\Omega \rangle = (-1)^{\binom{m}{2}} \delta_{\Lambda\Omega} z_{\Lambda^s}.$$

This scalar product is equivalent to

$$\langle s_\Lambda^*, s_\Omega \rangle = \delta_{\Lambda\Omega},$$

where $s_\Lambda^* := (-1)^{\binom{m}{2}} \omega(\bar{s}_{\Lambda'})$ and ω being the involution defined as [1, Corollary 29]

$$\omega(p_r) = (-1)^{r-1} p_r, \quad \omega(\tilde{p}_{r-1}) = (-1)^{r-1} \tilde{p}_{r-1}.$$

Now, if we define a new basis H_Λ given by $H_\Lambda := \tilde{p}_{\Lambda^a} h_{\Lambda^s}$, we observe that

$$\langle s_\Lambda^*, H_\Omega \rangle = K_{\Lambda\Omega},$$

or, equivalently

$$H_\Lambda = \sum_{\Omega \geq \Lambda} K_{\Omega\Lambda} s_\Omega. \tag{6.1}$$

Setting $\Lambda = (n;)$ in the previous relation implies that $\tilde{p}_n = s_{(n;)}$. Indeed, $(n;)$ is the largest superpartition with degree $(n|1)$ so that there is a single contributing term in the sum, and its coefficient is $K_{\Lambda\Lambda} = 1$. The equation (6.1) can thus be written as

$$s_{(\Lambda_1;)} \cdots s_{(\Lambda_m;)} s_{(; \Lambda_{m+1})} \cdots s_{(; \Lambda_N)} = \sum_{\Omega \geq \Lambda} K_{\Omega\Lambda} s_\Omega.$$

This implies that by using the Pieri rules for multiplication of rows corresponding to the parts of the superpartition Λ , the number of admissible Pieri diagrams (erasing the filling) equal to Ω must be identical to the number of dual semi-standard tableaux of shape Ω and content Λ , which is precisely the number $K_{\Omega\Lambda}^c$ from Conjecture 5.1. Note that this connection ensures the positivity of the Pieri rule, which is not manifest from (4.4) (but see the remark below).

In order to make this connection more precise, let $P^\circ(\Lambda)$ be the set of all admissible Pieri tableaux resulting from successive row multiplications, the rows corresponding to the parts of the superpartition Λ

$$(; \Lambda_{m+1}) \otimes \cdots \otimes (; \Lambda_\ell) \otimes (\Lambda_1;) \otimes \cdots \otimes (\Lambda_m;). \tag{6.2}$$

In this multiple product, the order is taken to be from left to right. We thus start row multiplications in the bosonic sector and end up with the multiplication of the fermionic rows.

As an illustrative example of such computations, consider $P^\circ((0; 1^3))$. Let the row associated with Λ_i be marked with number i . The first step, the bosonic-row multiplications, yields

$$(\begin{smallmatrix} 2 \\ 3 \end{smallmatrix} \otimes \begin{smallmatrix} 3 \end{smallmatrix}) \otimes \begin{smallmatrix} 4 \end{smallmatrix} = \left(\begin{smallmatrix} 2 \\ 3 \end{smallmatrix}, \begin{smallmatrix} 2 & 3 \end{smallmatrix} \right) \otimes \begin{smallmatrix} 4 \end{smallmatrix} = \begin{smallmatrix} 2 & 4 \\ 3 \end{smallmatrix}, \quad \begin{smallmatrix} 2 \\ 3 \\ 4 \end{smallmatrix}, \quad \begin{smallmatrix} 2 & 3 & 4 \end{smallmatrix}, \quad \begin{smallmatrix} 2 & 3 \\ 4 \end{smallmatrix}.$$

Next, the multiplication with the sole fermionic row $(0;)$ gives

$$\begin{array}{cccccc} \begin{smallmatrix} 2 & 4 & \textcircled{1} \\ 3 \end{smallmatrix}, & \begin{smallmatrix} 2 & 4 \\ 3 & \textcircled{1} \end{smallmatrix}, & \begin{smallmatrix} 2 & 4 \\ 3 \\ \textcircled{1} \end{smallmatrix}, & \begin{smallmatrix} 2 & \textcircled{1} \\ 3 \\ 4 \end{smallmatrix}, & \begin{smallmatrix} 2 \\ 3 \\ 4 \\ \textcircled{1} \end{smallmatrix}, & \\ \begin{smallmatrix} 2 & 3 & 4 & \textcircled{1} \end{smallmatrix}, & \begin{smallmatrix} 2 & 3 & 4 \\ \textcircled{1} \end{smallmatrix}, & \begin{smallmatrix} 2 & 3 & \textcircled{1} \\ 4 \end{smallmatrix}, & \begin{smallmatrix} 2 & 3 \\ 4 & \textcircled{1} \end{smallmatrix}, & \begin{smallmatrix} 2 & 3 \\ 4 \\ \textcircled{1} \end{smallmatrix}. & \end{array} \quad (6.3)$$

This relationship entails another combinatorial definition of the Kostka numbers $K_{\Lambda\Omega}$.

Conjecture 6.1. *We have*

$$K_{\Lambda\Omega} = \sum_{T^\circ \in P^\circ(\Omega, \Lambda)} (-1)^{\text{inv}(T^\circ)},$$

where $P^\circ(\Lambda, \Omega)$ is the set of tableaux of $P^\circ(\Lambda)$ that have shape Ω and $\text{inv}(T^\circ)$ is the minimal number of permutations needed to reorder the fermionic set in T° from top to bottom in increasing order.

By Conjecture 5.1, this corresponds to the number of dual super semi-standard tableaux, which are enumerated by $K_{\Lambda\Omega}^c$. In the above example (cf. (6.3)), we have displayed the dual super semi-standard tableaux with content $(0; 1^3)$ for all superpartitions of degree $(3|1)$. As another example, consider $P^\circ((2, 1; 1^3), (3, 2; 1))$; it is given by the tableaux:

$$\begin{array}{cccccc} \begin{smallmatrix} & 1 & 1 & \textcircled{1} \\ & 2 & \textcircled{2} \\ \end{smallmatrix}, & \begin{smallmatrix} & & 1 & \textcircled{1} \\ & 1 & \textcircled{2} \\ 2 \end{smallmatrix}, & \begin{smallmatrix} & & 2 & \textcircled{2} \\ & 1 & \textcircled{1} \\ 1 \end{smallmatrix}, & \begin{smallmatrix} & & 1 & \textcircled{1} \\ & 2 & \textcircled{2} \\ 1 \end{smallmatrix}, & \begin{smallmatrix} & & & \textcircled{1} \\ 1 & 1 & \textcircled{2} \\ 2 \end{smallmatrix}, & \begin{smallmatrix} & & & \textcircled{2} \\ 1 & 1 & \textcircled{1} \\ 2 \end{smallmatrix}, \\ 1 & 2 & -2 & 2 & 1 & -1 \end{array}$$

where the multiplicity below each tableau corresponds to the number of standard fillings of the empty boxes with the omitted numbers 3, 4, 5 times $(-1)^{\text{inv}(T^\circ)}$. Summing all contributions gives a total of 3 which is precisely the value of $K_{(3,2;1),(2,1;1^3)}$.

Remark. The ordering used in (6.2) is motivated by the ordering fixed by Rule 5.1. However, we can construct the Pieri tableaux using a different multiplication order, for instance, beginning with the multiplication of fermionic rows and taking the usual number ordering: $1 < 2 < \dots < m < m+1 < \dots$ (and distinguishing this set of tableaux with a tilde):

$$\tilde{P}^\circ(\Lambda) : (\Lambda_1;) \otimes \dots \otimes (\Lambda_m;) \otimes (; \Lambda_{m+1}) \otimes \dots \otimes (; \Lambda_\ell)$$

(multiplying as usual from left to right). One advantage of this procedure is that the product of the m fermionic rows generate a single tableau with a positive sign. Because the remaining multiplication of bosonic rows is manifestly positive, this ensures the positivity of the super-extension of the Pieri rules. This gives another combinatorial definition for the dual super

semi-standard tableaux: $K_{\Omega\Lambda}$ is given by the cardinality of the set $\tilde{P}^\circ(\Lambda, \Omega)$. For the above example, $\Lambda = (2, 1; 1^3)$ and $\Omega = (3, 2; 1)$, after the first step one has

$$\begin{array}{|c|c|c|} \hline 1 & 1 & \textcircled{1} \\ \hline 2 & \textcircled{2} & \\ \hline \end{array} \otimes \begin{array}{|c|} \hline 3 \\ \hline \end{array} \otimes \begin{array}{|c|} \hline 4 \\ \hline \end{array} \otimes \begin{array}{|c|} \hline 5 \\ \hline \end{array},$$

which gives for $\tilde{P}^\circ((2, 1; 1^3), (3, 2; 1))$:

$$\begin{array}{|c|c|c|c|} \hline 1 & 1 & 3 & \textcircled{1} \\ \hline 2 & 4 & \textcircled{2} & \\ \hline 5 & & & \\ \hline \end{array}, \quad \begin{array}{|c|c|c|c|} \hline 1 & 1 & 3 & \textcircled{1} \\ \hline 2 & 5 & \textcircled{2} & \\ \hline 4 & & & \\ \hline \end{array}, \quad \begin{array}{|c|c|c|c|} \hline 1 & 1 & 4 & \textcircled{1} \\ \hline 2 & 5 & \textcircled{2} & \\ \hline 3 & & & \\ \hline \end{array}.$$

This ordering could be used to formulate new rules for the construction of dual super semi-standard tableaux (rules which we have not found however). But we then lose the connection with the usual Kostka numbers that enumerate the filling of the reduced tableaux obtained once the fermionic numbers have been introduced (cf. Example 5.1 and (3.5) for a similar result in the non-dual context), which connection is a great computational advantage.

A Superpartitions and symmetric superpolynomials

In this first appendix, we summarize the basic notions and definitions pertaining to symmetric superpolynomials.

A.1 Superpartitions

Superpartitions are generalizations of regular partitions and are the combinatorial objects used to label symmetric superpolynomials. We first give the following definition.

Definition A.1 (superpartition: the $(\Lambda^a; \Lambda^s)$ description). A superpartition Λ is a pair of partitions [5]

$$\Lambda = (\Lambda^a; \Lambda^s) = (\Lambda_1, \dots, \Lambda_m; \Lambda_{m+1}, \dots, \Lambda_\ell),$$

such that

$$\Lambda_1 > \dots > \Lambda_m \geq 0 \quad \text{and} \quad \Lambda_{m+1} \geq \Lambda_{m+2} \geq \dots \geq \Lambda_\ell > 0.$$

We stress that Λ^a has distinct parts and the last part is allowed to be 0. The number m is called the fermionic degree of Λ and $n = |\Lambda| = \sum_i \Lambda_i$ is the bosonic degree. Such superpartition Λ is said to be of degree $(n|m)$, which is denoted as $\Lambda \vdash (n|m)$.

The diagrammatic representation of superpartitions is very similar to the usual Young diagrams representing partitions. By removing the semi-coma and reordering the parts of Λ , we obtain an ordinary partition that we denote Λ^* . The diagram of Λ is that of Λ^* with circles added to the rows corresponding to the parts of Λ^a and ordered in length as if a circle was a half-box [7]. Here is an example of a superpartition with degree $(27|5)$:

which corresponds to $\Lambda = (8, 6, 3, 2, 0; 5, 3)$. Each box and circle in the diagram of Λ can be identified by its position $s = (i, j)$, where i denotes the row, numbered from top to bottom, and j denotes the column, numbered from left to right. A row or column ending with a circle is dubbed *fermionic*. Other rows and columns are said to be *bosonic*. In the above diagram, the box with a \star has position $s = (4, 3)$; it belongs to the third fermionic row and the second fermionic column. With this diagrammatic representation, it is simple to define the conjugate operation.

Definition A.2 (conjugate superpartition). The diagram of the superpartition Λ' conjugate of Λ is obtained by interchanging the rows and columns of the diagram Λ .

For example,

$$\left(\begin{array}{|c|c|c|} \hline \square & \square & \circ \\ \hline \circ & & \\ \hline \end{array} \right)' = \begin{array}{|c|} \hline \square \\ \hline \square \\ \hline \circ \\ \hline \end{array} \Rightarrow (20;)' = (1, 0; 1).$$

Definition A.3 (superpartition: the Λ^* , Λ^\circledast description). A superpartition Λ of degree $(n|m)$ is described by a pair of 2 partitions Λ^* , Λ^\circledast ,

$$\Lambda \Leftrightarrow \Lambda^*, \Lambda^\circledast$$

such that $|\Lambda^*| = |\Lambda^\circledast| - m = n$ and $\Lambda^\circledast/\Lambda^*$ is a skew diagram that is both a horizontal and vertical m -strip. Diagrammatically, Λ^* is obtained by removing all circles in Λ and Λ^\circledast is obtained by replacing all the circles by boxes.

Clearly, both definitions A.1 and A.3 completely characterizes Λ . For example, with $\Lambda = (4, 3, 0; 4)$:

$$\Lambda = \begin{array}{|c|c|c|c|} \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \end{array} \Leftrightarrow \Lambda^\circledast = \begin{array}{|c|c|c|c|} \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \end{array}, \quad \Lambda^* = \begin{array}{|c|c|c|c|} \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \square & \square & \square & \square \\ \hline \end{array}.$$

We now introduce the version of the dominance ordering that applies to superpartitions; it relies on the Λ^* , Λ^\circledast representation.

Definition A.4 (dominance order). We say that [8]:

$$\Lambda \geq \Omega \iff \Lambda^* \geq \Omega^* \quad \text{and} \quad \Lambda^\circledast \geq \Omega^\circledast,$$

where, recall that, the order on partitions is the usual dominance ordering:

$$\lambda \geq \mu \iff |\lambda| = |\mu| \quad \text{and} \quad \lambda_1 + \dots + \lambda_k \geq \mu_1 + \dots + \mu_k \quad \forall k.$$

Pictorially, $\Lambda \geq \Omega$ if Ω can be obtained from Λ successively by moving down a box or a circle. For example,

$$\begin{array}{|c|c|} \hline \square & \square \\ \hline \square & \square \\ \hline \end{array} \geq \begin{array}{|c|} \hline \square \\ \hline \square \\ \hline \square \\ \hline \end{array} \quad \text{but} \quad \begin{array}{|c|c|} \hline \square & \square \\ \hline \square & \square \\ \hline \end{array} \not\geq \begin{array}{|c|c|c|} \hline \square & \square & \square \\ \hline \square & & \\ \hline \end{array} \quad \text{and} \quad \begin{array}{|c|c|c|} \hline \square & \square & \square \\ \hline \square & & \\ \hline \end{array} \not\geq \begin{array}{|c|c|} \hline \square & \square \\ \hline \square & \square \\ \hline \end{array}.$$

In the latter two cases, the superpartitions are non-comparable.

A.2 Symmetric superpolynomials

Superpolynomials are polynomials in the usual commuting N variables x_1, \dots, x_N and the N anticommuting variables $\theta_1, \dots, \theta_N$. Symmetric superpolynomials are invariant with respect to the interchange of $(x_i, \theta_i) \leftrightarrow (x_j, \theta_j)$ for any i, j [5].

The space of symmetric superpolynomials, denoted $\mathcal{R}^{S_N} = F[x, \theta]^{S_N}$ where F is some field, is naturally graded:

$$\mathcal{R}^{S_N} = \bigoplus_{n,m} \mathcal{R}_{(n|m)}^{S_N},$$

where $\mathcal{R}_{(n|m)}^{S_N}$ is the space of homogeneous symmetric superpolynomials of degree n in the x variables and degree m in the θ variables. Bases of $\mathcal{R}_{(n|m)}^{S_N}$ are labelled by superpartitions of degree $(n|m)$. We now present the superpolynomial version of the classical bases [7].

Definition A.5 (super-monomials). The super-version of the monomial function (1.2) reads:

$$m_\Lambda(x, \theta) = \theta_1 \cdots \theta_m x_1^{\Lambda_1} \cdots x_N^{\Lambda_N} + \text{distinct permutations of } (x_i, \theta_i) \leftrightarrow (x_j, \theta_j).$$

(Here and elsewhere, it is understood that $\Lambda_{\ell+1} = \cdots = \Lambda_N = 0$.)

Here is an example, for $N = 4$:

$$\begin{aligned} m_{(1,0;1,1)}(x; \theta) &= \theta_1 \theta_2 (x_1 - x_2) x_3 x_4 + \theta_1 \theta_3 (x_1 - x_3) x_2 x_4 + \theta_1 \theta_4 (x_1 - x_4) x_2 x_3 \\ &\quad + \theta_2 \theta_3 (x_2 - x_3) x_1 x_4 + \theta_2 \theta_4 (x_2 - x_4) x_1 x_3 + \theta_3 \theta_4 (x_3 - x_4) x_1 x_2. \end{aligned}$$

Another example illustrating the fact that Λ_m is allowed to be 0 is $m_{(0;3)}$, written here for $N = 2$:

$$m_{(0;3)}(x; \theta) = \theta_1 x_2^3 + \theta_2 x_1^3.$$

Definition A.6 (multiplicative bases). For a superpartition Λ , we have the following multiplicative basis

$$f_\Lambda = \tilde{f}_{\Lambda_1} \cdots \tilde{f}_{\Lambda_m} f_{\Lambda_{m+1}} \cdots f_{\Lambda_\ell},$$

where f_Λ stands for:

1) the super-power-sums:

$$\tilde{p}_r = \sum_i \theta_i x_i^r \quad \text{and} \quad p_s = \sum_i x_i^s, \tag{A.1}$$

2) the elementary superpolynomials:

$$\tilde{e}_r = m_{(0;1^r)} \quad \text{and} \quad e_s = m_{(1^s)},$$

3) the completely homogeneous symmetric superpolynomials:

$$\tilde{h}_r = \sum_{\Lambda \vdash (r|1)} (\Lambda_1 + 1) m_\Lambda \quad \text{and} \quad h_s = \sum_{\lambda \vdash (s|0)} m_\lambda$$

In the three cases, we have $r \geq 0$ and $s \geq 1$.

B Bilinear identities in superspace

We end this article with the presentation of a series of bilinear identities for Schur superpolynomials. They generalize the bilinear identity for the standard rectangular-type Schur polynomials found in [12]:

$$s_{(k^n)} s_{(k^n)} = s_{((k+1)^n)} s_{((k-1)^n)} + s_{(k^{n+1})} s_{(k^{n-1})}, \quad (\text{B.1})$$

where as usual k^n means that the part k is repeated n times. This identity can be represented diagrammatically as (with $k = 3$ and $n = 2$)

This (remarkable) identity is equivalent to the Dodgson's condensation formula (also known as the Desnanot–Jacobi matrix theorem), which reads (see, e.g., [4])

$$\det(M_1^1) \det(M_\ell^\ell) = \det(M_1^\ell) \det(M_\ell^1) + \det(M) \det(M_{1,\ell}^{1,\ell}), \quad (\text{B.2})$$

where M is a $\ell \times \ell$ matrix and M_i^j refers to M with the i -th line and the j -th column removed. The relation between (B.2) and (B.1) follows from the definition of Schur function in terms of a determinantal formula.

We now consider generalizations of (B.1) for the Schur superpolynomials. Note that tentative proofs along the above lines are bound to fail due to the absence of determinantal formula for superpolynomials. Here, a rectangular diagram can be extended in different ways by the adjunction of circles. For example for the above diagram (3^2) is generalized by the following four super-diagrams (for which either Λ^* or Λ^\otimes is rectangular):

Conjecture B.1. *Let k, n be integers with $k > 1$ and $n > 1$. Let $r', r \in \{k, k-1, 0\}$ with $r' > r$ and $\epsilon = \delta_{r,0}$. We have*

$$s_{(r;k^{n-1+\epsilon})} s_{(k^n)} = s_{(r+1-\epsilon;k+1)^{n-1+\epsilon}} s_{((k-1)^n)} + s_{(r;k^{n+\epsilon})} s_{(k^{n-1})}, \quad (\text{B.3})$$

$$s_{(r';k^{n-1})} s_{(r;k^{n-1+\epsilon})} = s_{(r'+1,r+1-\epsilon;k+1)^{n-2+\epsilon}} s_{((k-1)^n)} + s_{(r',r;k^{n-1+\epsilon})} s_{(k^{n-1})}, \quad (\text{B.4})$$

$$s_{(k,0;k^{n-1})} s_{(k^n)} = s_{(k+1,0;k+1)^{n-1}} s_{((k-1)^n)} + s_{(k,0;k^n)} s_{(k^{n-1})}. \quad (\text{B.5})$$

Note that in the first two cases, each identity is a compact formulation for three identities as there are three ways of selecting the pair (r, r') . For example, the identity (B.4) with $k = 3$, $n = 2$ and $r' = 3, r = 2$ reads

For the same values of k and n , the diagrammatic form of (B.5) is

In addition, similar bilinear identities have been found for almost rectangular-type super-diagrams, namely

for which neither Λ^* nor Λ^{\otimes} rectangular.

Conjecture B.2. *We have*

$$S(k, k-1; k^{n-2}) S(k^n) = -S(k+1, k; (k+1)^{n-2}) S((k-1)^n) + S(k-1; k^n) S(k; k^{n-2}), \quad (\text{B.6})$$

$$S(k-1, 0; k^{n-1}) S(k^n) = S(k-1, 0; (k+1)^{n-1}) S((k-1)^n) + S(k-1; k^n) S(0; k^{n-1}), \quad (\text{B.7})$$

$$S(k, k-1; k^{n-2}) S(0; k^n) = S(k+1, k, 0; (k+1)^{n-2}) S((k-1)^n) + S(k-1, 0; k^n) S(k; k^{n-2}), \quad (\text{B.8})$$

$$S(k, k-1, 0; k^{n-2}) S(k^n) = S(k+1, k; (k+1)^{n-2}) S(0; (k-1)^n) + S(k-1, 0; k^n) S(k; k^{n-2}). \quad (\text{B.9})$$

Still for the values $k = 3$ and $n = 2$, we illustrate the identities (B.8):

and (B.9):

Acknowledgements

We thank Luc Lapointe for useful discussions and critical comments on the manuscript. We also thank Patrick Desrosiers for his collaboration at the early stages of this project. This work is supported by NSERC and FRQNT.
